

Capstone Project

Assignment Type: Group/Collaborative

Total Marks: 100

Deadline: 6th June, 2026

Submission: [Submit here](#) - Project repository and deployment link

This is a group project, although submission will be on individual basis, simply provide the group git repo url when submitting.

Overview

This capstone project assesses your ability to apply the concepts covered throughout the courses' duration while working collaboratively in a team.

Over the past 3 months you have learned **HTML, CSS & Javascript (React)** along with concepts such as Fetch API (**promises**), **Responsive design**, and Git workflows. This project would help solidify it.

Your task is to recreate this [mockup](#) as a working web application using **React**. This is a buildup of what you have built with the HTML assignment but the implementation now involves the use of CSS, Dynamic data, Component-based approach and collaborative development.

Virtual peer coding is encouraged.

Learning objectives

The completion of this project would show that students have an understanding of:

1. HTML, CSS, JS fundamentals
2. Fetch API and working with external data
3. Functions and Logic
4. JSX syntax
5. React and component based architecture
6. Research and Documentation
7. Responsive Web Design
8. Git collaboration and Pull Request workflows
9. Deploying application to the hosting platform
10. Developing an application to match design provided

Requirements

Students will implement the following functionality while re-creating the mockup;

Existing Functionality

Please retain the following behaviours from the previous assignment;

1. The “Explore the Data” CTA must scroll to the section containing the planet images.
2. The <meta name=”author”> should contain the group name
3. The “contact us” call to action must scroll to the form section
4. The video to be used should not be embedded using an iframe, the video must **autoplay**, **be muted and loop**.

React

The application **must be built** using React. Components should be used to organise the interface. I would advise that all parts of the interface be a component, this would give room for everyone to participate. Example is the Hero.

Fetch API

Use the provided [API](#) to retrieve information about planets. The application should fetch and display;

- Planet name
- Distance from the sun
- Image

Ensure to use the <figure> element as learnt during HTML.

Forms

The form should submit data using this [endpoint](#). Retain all client-side form validation used during HTML assignment and show the user a message when form has been submitted.

Responsive Design

There is a slight modification for the mobile view, so achieving this demonstrates understanding of flexible layouts and media queries.

Hosting

The completed project must be deployed and publicly accessible. Teams are encouraged to use free hosting services such as Netlify or Vercel or any other similar platform.

Github

Each member of the team should have a git account.

The team lead should;

1. Create a public repository named after the group.
2. Add all team members as collaborators.

The creator of a PR must not be the person who reviews and merges it. Avoid unnecessary commits and PRs - ensure you have finished a task to the required expectation before creating a PR..

Footer

1. The about section should contain a brief description of the team, maybe first names of each member.

The following text should link to;;

2. Amaka with <https://amakandukwu.com/>
3. Ifeoma with - <https://www.linkedin.com/in/ifeomaokocha>
4. TSacademy - <https://tsacademyonline.com/>
5. Groupname - links to the group's repo

Team Leads Responsibilities

The team lead should appoint one more person as an assistant team lead. The team lead is responsible for coordinating the work of the group and ensuring there is a smooth progression. This role is very organizational and ensures structure is maintained.

Documentation

The team lead is responsible for ensuring that the repository contains a README file that includes:

- A brief summary of the project
- The names of all group members with links to their Github profile
- The components or functions - who worked on it, if it's a group highlight it.
- The instruction on how to run the project locally
- The live deployment link - *this can be updated towards the end of the project.*

Git workflow

1. Work should be done on separate branches
2. Contributions should be submitted through Pull requests
3. The person who opens a PR should not review and merge their own PR
4. PR must be reviewed before being merged into the main branch
5. You can use the projects feature of Github to manage tasks

Projects

Task Distribution

1. Help organise the project into tasks or components
2. Ensure responsibilities are clearly defined and distributed among members.
3. Monitor progress to know who is active or not active.

The team lead has to set the ground rules.

Final Notes

You would be assessed as a Group and on individual contribution.
